**Empirical Study of Sorting Algorithms** 

April 29, 2020

## **An Empirical Study: Sorting Algorithms**

The following empirical study compared runtime efficiency for 3 sorting algorithms: mergesort, quicksort and heapsort, each implemented in python. Each algorithm was tested on 270 files of randomly generated integers in 3 formats, unsorted, sorted, and reverse-sorted. Groups are labeled: small, medium and large where n was 10,000, 100,000, and 1,000,000 respectively. Each group of test data represents best, average and worst case and allows us to measure the runtime efficiency for each case respectively. The theoretical time complexity analysis for each algorithm is shown below.

| Time Complexity | Best               | Average            | Worst      |
|-----------------|--------------------|--------------------|------------|
| Mergesort       | $\Omega(n \log n)$ | $\Theta(n \log n)$ | O(n log n) |
| Quicksort       | $\Omega(n \log n)$ | $\Theta(n \log n)$ | $O(n^2)$   |
| Heapsort        | $\Omega(n \log n)$ | θ(n log n)         | O(n log n) |

Each time complexity above ignores constant factors and therefore we may expect a competitive analysis when each algorithm is run on the test data. However these constant factors do play a role in practice and can be observed when each implementation is compared side by side.

In the best case when the array was sorted, quicksort had the most efficient runtime while heapsort the least. All 3 algorithms have equivalent time complexities, however we see an evident discrepancy in constant factors which results in different runtime efficiencies. In the average case where the array is not sorted, quicksort beat both mergesort and heapsort. In both the best and worst cases, quicksorts' performance can be attributed to the reduced amount of logic that is executed recursively. Quicksorts' strategy of dividing the problem to its simplest pieces recursively, as opposed to mergsorts' more linear approach, and then constructing the solution from smaller solutions is an effective improvement to mergesort. In the worst case where the array is in reverse sorted order, mergesort ran more efficiently with the exception of medium sized inputs. It is worth noting that although quicksort has a worst case time complexity of  $O(n^2)$ , our median-of-three approach to picking a pivot value resulted in a much faster runtime. Quicksort's true worst case would have been a reverse sorted array where the pivot is always the leftmost or rightmost value. As such, a median-of-three implementation to quicksort showed competitive results against the other 2 sorting algorithms. Heapsort did not show it's superior performance in this empirical study. In

implementing the algorithm, it is evident why this may be the case. Heapsort is guaranteed to swap every single element in the heap, while other sorting algorithms, such as quicksort avoid unnecessary swaps.

In conclusion of this study, the data supports the argument that quicksort, although a slower time complexity in the worst case of  $O(n^2)$ , with a more efficient pivot selection we can improve its performance to beat even merge sort which has a worst case of  $O(n \log n)$ .

| Key              |         |  |  |  |
|------------------|---------|--|--|--|
| Small: 10,000    |         |  |  |  |
| Medium: 100,000  | Fastest |  |  |  |
| Large: 1,000,000 | Slowest |  |  |  |
